It can enable you to adjust the video resolution, 10. Operating system – An operating system, also known as a computer operating system, is the set of fundamental software programs that constitute the interface between the computer hardware and the user of the computer. The operating system is responsible for mediating and controlling access to hardware and it is the software component that gives the computer system its ability to interact with and control other devices and computer systems. Some examples of common operating systems are Microsoft Windows, Linux, macOS. The operating system is the layer of the computing model that interacts directly with users and their applications, other layers include the hardware, device drivers, and middleware and the network and security layers. A single-user operating system is designed specifically for one computer and a multi-user operating system is designed to support several concurrent users. One type of operating system is a real-time operating system, the main type of operating system in widespread use today is the non-real-time operating system, which is dominated by Microsoft Windows and macOS. An operating system is a layer of abstraction above the hardware, running on a computer, an operating system consists of a kernel and a set of system software programs. The kernel is a central component in the operating system, and it manages computer resources and provides services to support the running of applications. In contrast, the system software provides user interfaces and data management, an application that runs on an operating system is known as an application program, or simply a program. An operating system must meet three goals, offer services to applications, shield applications from the details of the computer hardware, provide a standard interface between the operating system and hardware, an application may only be able to use the functions the operating system allows. The organization of an operating system is hierarchical, a single computer may have many separate instances of an operating system running simultaneously. An operating system is a part of a larger system, a computing platform. For a system to function as a whole, it must work together, a computing platform may use either a monolithic kernel or a modular kernel, the latter being a type of microkernel. A monolithic kernel is a kernel that is designed to service a complete platform, one of the main objectives of a monolithic kernel is the isolation of individual device drivers from the kernel and other drivers, in order to make device driver updates and maintenance easier. As a result, device drivers need to be updated by the manufacturer of the hardware, many operating systems are designed to work well with the x86 microprocessor 82157476af
